Mystery over the Paris airport collapse

By Kate Milner
BBC News Online

Structural engineers are baffled by what might have caused the roof collapse at Paris' Charles de Gaulle-Roissy airport, which killed four people.

The ultra-modern Terminal 2E, which opened 11 months ago, was built using steel, concrete and 36,000 sq m (118,116 sq ft) of reinforced glass.

It consists of two long tunnel-like buildings connected by a central passageway.

The part that collapsed was a 30-metre (98-foot) section of roof on the outer building, where passengers wait before boarding the aircraft.

The investigation into what went wrong will focus primarily on whether there was a fault in the design of the building, or whether short cuts had been taken when it was built.

The internationally-renowned French architect who designed the terminal, Paul Andreu, has described the structure as "bold" but "nothing revolutionary".

Charles de Gaul Airport

"The structure stood for a year and then spontaneously fell down without anything apparently changing. It's very odd"

"Buildings like that do not just collapse", leading structural engineer Professor Chris Wise told BBC News Online.

"Something very unusual has happened," he said.

So could a mistake have slipped through?

"There are lots of checks and balances in a project like this", Professor Wise said. "If you make a mistake with the design there's almost no chance of your design getting built. Somebody along the way would find it."

A380 Economics

- Cost of an A380 +/- \$240 Million
- Airbus need to sell +/- 300 to break even
 - \$72 billion to break even
- Development started in 1999
- First deliveries scheduled for 2006
- Currently have orders for 139
- How did they manage to sell 139 airplanes of a type that has never flown?

Testing the A380

Copyright (c) 2004 Verum Consultants BV

The Purpose of Testing

- Testing is **not** about finding out whether aircraft will fly.
 - It is tradition for Boeing's design team to always sit in on the inaugural flight of a new aircraft type
- Testing is not about removing Requirements, Architecture or Major Design Defects
 - It would be economic death for the A380 if it were
- Testing is largely about confirming what they already know.
- Confirming what they know is all about Predictability

Why do Aircraft Fly?

- Because, apart from everything else, Aircraft Designers and Aeronautical Engineers make routine, systematic use of mathematics to describe and control the complexity of their product.
- Aircraft Designers and Aeronautical Engineers are taught to make use of mathematics to describe complexity from the moment they enter higher education.
- The Aeronautical Engineering world makes use of the conventions, tools and mathematical techniques developed by Universities and taught to their students

Circuit Engineering¹

- Born in 1938 as a result of a paper by Claude Shannon
- Recognized that a circuit is a rule for a function
 - Boolean Function
- Hardware was expensive
 - Repairs cost both money and time
- Talented Mathematicians & Engineers fully exploited Boolean Algebra to prevent defects.
- Theorems showed it possible to build any function from NAND gates
 - Highly economical approach

Circuit Engineering History

- Mathematicians produced normal forms for functions using specific operators
- Notation lead to exact correspondence between diagrams and circuits
- Engineers designed larger units mathematically & constructed them physically
- Units evolved into components and reuse was born.
 - Based on exact functional descriptions of the unit
 - Streamlined innovation, based on catalogs of components
- By 1980's complexity had increased state space enormously, yet could be treated explicitly

Circuit Engineering Today

- Adheres to a description of components assembled according to the mathematics of functional composition
- Is still mostly a matter of forward design using established components and leaving a documented design trail.
- The complexity of circuit engineering matches or exceeds that of any other field.

Conclusion

- In the field of Engineering most closely related to Software Engineering
- Mathematics has grown up hand-in-hand with design and implementation from the very earliest days
- As a result Circuit Engineers are able to manage the complexity of sophisticated components
- They are able to design and verify the designs of these components
- And the results of Circuit Engineering are highly predictable in comparison with its complexity.

Making Software Fly

- Software Engineering must:
 - adopt methods and techniques that are routine for every other branch of engineering
 - must embrace the use of mathematics at all levels of education & industry
- Specifically:
 - Business Critical Software must be based on designs that are verifiably correct before implementation
 - Software Architects and Designers must limit themselves to designs that can be verified
- These things are now economically possible
